Acknowledgments

This volume represents the Office of Statewide Health Planning and Development's first hospital outcomes report produced by an in-house team. It draws upon the expertise of four new staff members--Steven Lubeck, Ph.D., Victor Simon, Yuan Qing (Cliff) Li, M.P.H., and Louise Hand--and benefits from Andra Zach's and Mary MacDonald's prior collaboration with university-based researchers on earlier reports.

The Office owes a substantial debt to Harold Luft, Ph.D., and Patrick Romano, M.D., M.P.H., who developed the original risk-adjustment models described in this report. We are also indebted to the programming staffs at U.C. San Francisco, U.C. Davis and U.C.L.A. who developed the computer programs used in earlier AMI reports. This volume profited from the considerable prior efforts of previous project teams.

Report on Heart Attack Outcomes in California: 1996 - 1998

The California Hospital Outcomes Project is an initiative mandated by the State of California, and conducted by the Office of Statewide Health Planning and Development (OSHPD), to develop public reports comparing hospital outcomes for selected conditions treated in hospitals throughout the state.

The Report on Heart Attack Outcomes is intended to encourage all California hospitals to improve their care and give credit to the hospitals that are the leaders. It can also help insurers, employers, and consumers to select hospitals based on quality of care.

The California Hospital Outcomes Project

Heart attacks (acute myocardial infarctions or AMI) were chosen as one of the first conditions to be reported upon by the California Hospital Outcomes Project because they are important, common, and deadly. Every year approximately 40,000 heart attack patients are admitted to 400 California hospitals. More than 5,000 of these persons die.

The mortality rates published in previous heart attack reports have been used in many ways. Hospitals have used their results to evaluate and improve their quality of care. Payers have used the reports to contract with the best hospitals. Consumers have used the reports to make more informed decisions.

The results published in this report are useful because:

- **They have been risk-adjusted.** Patient age, gender, type of heart attack, and chronic diseases were used to adjust for differences in patient risk when calculating hospital mortality rates.
- **They have been validated.** A major validation study involving nearly 1,000 heart attacks at 30 hospitals showed that variations in how hospitals report their data to OSHPD do not significantly affect their risk-adjusted death rates. In general, low-mortality hospitals treat heart attacks more aggressively than high-mortality hospitals.

Content of the Report on Heart Attack Outcomes

This report is the most recent in a series that began in 1993. This report includes heart attack cases from 1996 through 1998. It incorporates improvements in the risk-adjustment methodology introduced in earlier reports, including:

- Linking with Vital Statistics records to ascertain deaths occurring outside the hospital,
- Refining certain patient risk factor definitions based on the findings of the validation study published 1996; and
- Using six months of pre-heart attack hospital records to more completely describe patient risk factors.

This report consists of four volumes:

The **User's Guide** (Volume 1) is intended for all those interested in hospital performance including hospital staff, employers, government agencies, health plans, and insurance companies. This volume provides a brief description of the study background and methods. It also contains two tables that display the results for individual hospitals based on heart attacks that occurred between 1996 and 1998.

The **Technical Guide** (Volume 2) is intended for health services researchers, health care providers, and others interested in the statistical methods used to calculate risk-adjusted death rates.

The **Detailed Statistical Results** (Volume 3) contains the numerical results for individual hospitals upon which the classifications in the User's Guide are based. In addition, there are tables that aggregate the results to the county level. It also contains a graphical representation of both individual hospital and county-wide results, which can be used to examine annual trends.

The **Hospital Comment Letters** (Volume 4) is intended to give readers of the *Report on Heart Attack* an appreciation of its strengths and weaknesses from the hospitals' perspectives.

To obtain these volumes of the report contact:

Office of Statewide Health Planning and Development
Healthcare Information Resource Center
818 K Street, Room 500
Sacramento, CA 95814
(916) 322-2814

Documents excluding the *Hospital Guide*, are also available on the internet at <http://www.oshpd.state.ca.us>

Hospitals were provided with a *Hospital Guide* several weeks before the *Report on Heart Attack Outcomes* was published. This document accompanied each hospital's patient-specific data. Hospitals used this document to access and use their patient-specific data and to prepare their comment letters, provided in Volume 4. More importantly, hospitals and their physicians can use this information to target areas where heart attack care might be improved.

Section

1

Using this Volume

This document describes the hospital-specific statistics developed by the California Hospital Outcomes Project and discusses appropriate ways to use these statistics. The statistics are available in two media: as part of this document, which contains one table for each hospital beginning on page 19, or in a file available on OSHPD's web page (www.oshpd.state.ca.us/hpp/chop) which contains one record for each hospital and one record for each county. The only difference between the two versions is that the printed version presents numbers that are rounded off to have fewer digits.

Relationship to Other Volumes of this Report

The purpose of this volume of the *Report on Heart Attack Outcomes* is to provide and explain the detailed statistics associated with heart attack (i.e., acute myocardial infarction or AMI) mortality in California hospitals. It also suggests appropriate uses for these detailed data and explains why certain uses would be inappropriate.

The *User's Guide* (Volume 1) describes the data and summarizes the methods used in the analysis of risk-adjusted heart attack mortality. Statistical methods were used to determine whether each hospital's AMI death rate was significantly higher or lower than the general AMI death rate for the State. The results, using aggregated 1994-1996 data, are presented in two charts in the *User's Guide*. The first chart classifies each hospital into one of four categories. The second chart displays these risk-adjusted death rates graphically.

The *Technical Guide* (Volume 2) presents a detailed description of the data and of the risk-adjustment methods. This detailed methodological presentation is intended to allow users and researchers to review and comment on the approaches taken and to encourage improvements in the future.

As required by law, each hospital and its chief of medical staff were sent summaries of their own results and draft copies of the report. All hospital comments submitted in response to the draft report are included in *Hospital Comment Letters* (Volume 4). These responses should be reviewed carefully if the reader is interested in the results for particular hospitals.

Statistical Significance and Hospital Classification

The threshold of statistical significance used in this report of the California Hospital Outcomes Project is $p < 0.01$. This means that a hospital's risk-adjusted mortality rate was considered to be significantly lower or higher than

the general AMI death rate for the State if it was more extreme than what would be expected to occur by chance 1% of the time. Even if every hospital provided the same quality of care, chance variation in outcomes would mean that some hospitals would appear to be high outliers and some low outliers. With roughly 400 hospitals in the analysis, 1% or four would have higher than expected mortality due just to chance variation. Another four (1%) would have lower than expected mortality by chance. If about eight of the 400 hospitals were actually identified as outliers, one might conclude that none had quality of care problems, since this many outliers would be likely to occur just by chance.

In fact, 62 hospitals were identified as outliers for AMI mortality using Model A and 48 were identified as outliers using Model B. This distribution is inconsistent with the premise that all hospitals have equal quality. Without additional information from medical records, however, it is impossible to tell which of the outliers provided unusually good or poor quality care and which were outliers just due to chance.

A hospital is unlikely to be an outlier several years in a row just by chance. If this occurs, it probably reflects some consistent factors. Outcomes for AMI patients are based on cases admitted between January 1, 1996 and December 1, 1998. Overall mortality is reported as well as mortality for each of the three years separately. AMI outcomes for each year are calculated by applying the overall mortality model (which adjusts for the year of admission) to a single year's cases. Very few hospitals shift from being extreme low outliers in one year to extreme high outliers in the next. However, some hospitals with initially high mortality do improve over time, possibly because of improvements in quality of care. Similarly, some hospitals with initially low mortality appear to deteriorate over time. The graphs presented in this volume display these temporal trends, but the statistical significance of these trends at individual hospitals has not been assessed.

Section

2

Explanation of the Detailed Results

Hospital specific results are displayed in two ways. The detailed tables give the statistics upon which the summary results shown in the User's Guide are based. The charts present those results graphically.

The Tables, an Example

TABLE 1: Detailed Statistical Results for Acute Myocardial Infarction Mortality at a Hypothetical Hospital

Healthy County: General Hospital											
	Statewide Death Rate (%)	Number of Cases Included	Number of Observed Deaths	Number of Expected Deaths	Standard Deviation of Observed Deaths	Observed Death Rate (%)	Expected Death Rate (%)	Risk-Adjusted Death Rate (%)	Risk-Adjusted Death Rate: 95% Confidence Bounds		Probability This Rate Occurred by Chance
									Lower	Upper	
Model A All Years	12.1	750	108	98.5	8.8	14.4	13.1	13.3	11.1	15.4	0.152
1996	12.2	260	36	33.7	5.2	13.8	13.0	13.0	9.3	16.6	0.361
1997	12.0	247	38	32.0	5.0	15.4	12.9	14.3	10.6	18.0	0.137
1998	12.1	243	34	32.7	5.0	14.0	13.5	12.5	8.9	16.2	0.432
Model B All Years	12.1	747	108	99.5	8.1	14.5	13.3	13.1	11.2	15.1	0.164
1996	12.2	258	36	34.0	4.8	14.0	13.2	12.9	9.5	16.3	0.370
1997	12.0	246	38	31.6	4.6	15.4	12.9	14.5	11.0	17.9	0.104
1998	12.1	243	34	33.9	4.6	14.0	14.0	12.1	8.9	15.4	0.530

Table 1 summarizes the results for a hypothetical hospital. The first column on the left identifies the specific analytic model and the second column identifies the year(s) of data included in the results. The AMI outcome was death within 30 days of admission for the index AMI. Hospitals with no AMI patients in 1996-1998 are not included in this report. Because of specific data limitations described in Section 5 of the *Technical Guide*, 24 hospitals with AMI patients were excluded from the analysis in one or more of the three study years. An "Excluded" notation indicates that the data from a hospital in this year were excluded.

AMI results based on both Models A and B are presented for each hospital. These models are explained in general terms in the *User's Guide* and in detail in the *Technical Guide*. Sometimes slightly fewer patients were analyzed under Model B Than Model A. This is because some risk factors unique to Model B (e.g., race/ethnicity, insurance status) were unknown for some patients. When this occurred, that patient was omitted from the Model

B analysis. The omission of some cases from Model B causes a slight difference between the two models in the overall death rate.

The results are displayed year-by-year as well as for all years combined. For example, the results in a row labeled "1996" include only eligible patients discharged from the hospital for AMI in 1996. The row labeled "All Years" includes all eligible patients in 1996, 1997, and 1998 combined. Some hospitals do not have any AMI patients in a particular year, but do have patients in other years. In this case, the row corresponding to the year in which the hospital had no cases would be blank.

General Hospital in Healthy County, shown in Table 1, is used as an example for the following explanation of hospital-level summary statistics. The county-level tables in this volume include the same variables as the hospital-level tables described.

The Statewide Death Rate (%) is the total number of patients included in this report who died within 30 days of admission, divided by the total number of patients included in this report, multiplied by 100. As Table 1 shows, the overall *Statewide Death Rate* for AMI during 1996-1998 was 12.1%.

The column indicating Number of Cases Included tells how many cases from this hospital were included in the models. A general description of patient inclusion and exclusion criteria is in the *User's Guide*. A detailed description is in the *Technical Guide*, Section 2. Cases with missing data for one or more demographic variables included in Model B (such as race or source of payment) are not included in Model B. The overall number of AMI cases at General Hospital was 750 under Model A and 747 under Model B.

The Number of Observed Deaths is the number of patients at a facility who died within 30 days of admission for AMI. The death may have occurred at the index hospital, a transfer hospital, or outside the hospital setting. The full description of the outcome variable is given in Section 4 of the *Technical Guide*. At General Hospital, the overall *Number of Deaths* in the AMI analysis was 108 under both Model A and Model B.

The Number of Expected Deaths among patients included in the analysis is presented in the next column. The influence of patient characteristics on the risk of death was estimated from the statistical models described in the *Technical Guide*, Section 7. The predicted probability of death was computed for each patient. Summing these probabilities over all patients treated at a hospital gives the predicted number of deaths among those patients. At General Hospital, the *Number of Expected Deaths* was 98.5 using Model A and 99.5 using Model B.

The Standard Deviation of the Observed Deaths is the square root of the sum, over all of the included patients, of each patient's probability of death (p_i) times the probability of survival ($1-p_i$), i.e., $\text{SQRT}(\sum_i p_i(1-p_i))$. At General

Hospital, the *Standard Deviation of Observed Deaths* was 8.8 for Model A (all

years) and 8.1 for Model B (all years). Although the standard deviation of expected death was calculated, it did not affect the classification of hospital mortality and was therefore not used in the final analysis.

The Observed Death Rate (%) is the number of patients at this hospital who died, divided by the number of patients at this hospital included in the analysis, multiplied by 100. For example, under both Model A at General Hospital, the overall *Observed Death Rate* for AMI was $(108/750) \times 100$, or 14.4%.

The Expected Death Rate (%) is the expected number of patients at this hospital who died, divided by the number of patients at this hospital included in the analysis, multiplied by 100. General Hospital had 750 AMI patients included in Model A. With 98.5 patients expected to die, General Hospital has an *Expected Death Rate* under Model A of 13.1%.

The Risk-Adjusted Death Rate (%) is derived using a technique known as indirect standardization. It adjusts the observed death rate at the hospital to reflect what the rate would be if the patients were about as ill as "average" patients in the state. The *Risk-Adjusted Death Rate (%)* is calculated as the statewide rate, multiplied by the ratio of the number of *observed* deaths to the number of *expected* deaths at this hospital. This adjusted death rate can be used to compare the performance of different hospitals.

For example, the *Risk-Adjusted Death Rate* using Model A patients is the statewide rate (12.2%) times the observed number of deaths, divided by the expected number of deaths. At General Hospital under Model A, 108 patients died whereas 98.5 were expected to die. For General Hospital, the risk-adjusted death rate is $12.2\% \times (108/98.5) = 13.7\%$. Adjusting for its patient mix, General Hospital's risk-adjusted death rate is lower than its observed rate of 14.4%.

Note that the expected death rate (13.1%) is higher than the statewide rate (12.2%). This difference reflects the fact that patients at General Hospital had higher risk, on average, than the statewide population of patients. The risk-adjusted figure of 13.3% is an estimate of what the death rate would be at General Hospital if its patients matched the state average in terms of risk.

The Risk-Adjusted 95% Confidence Bounds reflect the level of confidence in the hospital's risk-adjusted death rate. Assuming that the risk model is correct, there is a 95% chance that the hospital's true risk-adjusted AMI death rate under Model A falls between the *Lower 95% Confidence Bound* of 11.1% and the *Upper 95% Confidence Bound* of 15.4%. Please note that this 95% confidence interval differs from the 98% confidence interval shown in the *User's Guide*. A narrower interval, providing 95% confidence rather than 98% confidence, is used in these tables for the benefit of individual hospitals and physician groups that are interested in evaluating their own performance. Wider confidence intervals are used to identify hospital outliers in the *User's Guide*, because of the large number of hospitals evaluated in the study.

The Probability This Rate Occurred by Chance is a measure of the likelihood that this many (or more) deaths occurred by chance, given the expected number of deaths from the risk-adjustment model. If the observed number of deaths is less than or equal to the expected number, a *lower p-value* is computed. If the observed number of deaths is more than the expected number, an *upper p-value* is computed.

The lower p-value is the probability of the observed number of deaths or fewer. The lower p-value represents a "test" of whether this hospital has systematically **better** outcomes than expected based on its patients' risk characteristics. A lower p-value of less than 0.05 indicates that there would be less than a 1 in 20 chance of this hospital having this few or fewer deaths, given its mix of patients, if quality of care were average.

The upper p-value is the probability of the observed number of deaths or more. The upper p-value represents a "test" of whether this hospital has systematically **worse** outcomes than expected based on its patients' risk characteristics. An upper p-value of less than 0.05 indicates that there would be less than a 1 in 20 chance of this hospital having this many or more deaths, given its mix of patients, if quality of care were average.

Because General Hospital had fewer deaths than expected in Model A, the lower p-value of 0.152 was used. Thus, in this hospital with 750 patients (and 13.3 expected deaths, based on Model A risk factors), the probability of observing 108 or fewer deaths due to chance alone is about 1 in 9 — a finding that tends to be consistent with chance variability. Such a finding provides little evidence that General Hospital's outcomes differ systematically from the statewide average.

The classification of hospitals into one of four categories, based on all three years of data, (as shown in the *User's Guide*) is based on a p-value of 0.01. Hospitals classified as significantly better than expected had fewer deaths than expected and a lower p-value of less than 0.01. Hospitals classified as significantly worse than expected had more deaths than expected and an upper p-value of less than 0.01.

Summarizing the contents of Table 1, General Hospital has an overall risk-adjusted death rate of 13.3% from Model A and 13.1% from Model B. These rates are higher than the overall statewide death rates but are not statistically significant. In the first table in the *User's Guide*, General Hospital would have been represented by a simple box (□) for both Model A and Model B in the results columns.

The Charts, an Example

Table 1 gave the detailed statistics for the fictional General Hospital in Healthy County. Figure 1 below displays General Hospital's yearly risk-adjusted death rates and the 95% confidence bounds around those rates.

FIGURE 1: Healthy County: General Hospital

Each table for a specific hospital or county is followed by two charts which graphically display the hospital's or county's risk-adjusted death rates from Model A and Model B, by year. The risk-adjusted death rates and 95% confidence bounds displayed in these charts are identical to those shown in the table on the same page.

The *User's Guide* includes a very similar display of hospitals' risk-adjusted death rates. However, the charts show overall results for 1996-1998 and feature 98% rather than 95% confidence bounds.

In the charts in this volume, annual risk-adjusted death rates for AMI patients are denoted by asterisks. As described above, the risk-adjusted death rate represents a measure of hospital performance adjusted for differences in patients' severity of illness across hospitals. Each risk-adjusted death rate is surrounded by 95% confidence bounds, which are denoted by thick dashes above and below each asterisk. There is a 95% chance that a hospital's true risk-adjusted death rate lies within the indicated range.¹

The statewide death rate is denoted by a horizontal dotted line. Note that the statewide death rate dropped from 12.3% in 1996 to 12.1% in 1997 and 1998. If the horizontal dotted line is below the hospital's lower confidence bound, then that hospital had a significantly higher than average risk-adjusted death rate, and significantly more deaths than were expected, in that year. If the statewide death rate lies above a hospital's upper confidence bound, then that hospital had a significantly lower than average risk-adjusted death rate, and significantly fewer deaths than were expected, in that year. For most hospitals, the statewide rate lies within the confidence bounds, indicating that the hospital's performance was within the expected range. This expected range is substantially wider when individual years are shown separately than when all three years are aggregated, as in the chart in the *User's Guide*.

Because two separate risk-adjustment models were developed to estimate the probability of death, the risk-adjusted death rate and confidence bounds from Model B are displayed next to the comparable data from Model A. If a specific hospital appears to have no point on the chart for one or more years, then that hospital either had no eligible cases or was excluded because of data limitations during that year or set of years. Volume 2, *Technical Guide*, Section 5 explains which hospitals were excluded because of data limitations. If a hospital had no eligible cases across all three years (1996-1998), then it is not listed in this volume.

¹. The confidence bounds shown in these charts are based on a widely used method called the normal approximation (see the 1997 *Technical Guide*, Section 11). For most hospitals, this procedure generated confidence bounds nearly identical to those implied by the exact method that was used to calculate p-values in the detailed statistical tables and to identify mortality outliers in the *User's Guide*. However, a few hospitals have 95% confidence bounds that do not include the statewide average, despite the fact that their exact p-value exceeds 0.025. The exact p-value is a more precise measure of the probability that a hospital's true risk-adjusted death rate equals the statewide average.

Section

3

How Not to Use These Results

*One might be tempted to use this set of hospital data tables to generate lists of the "best and worst" hospital in the state or in a particular community. This is **not** appropriate. Such listings or rankings are subject to substantial misinterpretation, stemming largely from the problem of chance variability discussed previously. This section discusses how to interpret the observed and expected death rates, and explains why ranking is inappropriate.*

Interpreting Death Rates

TABLE 2: AMI Data for a Hypothetical County

Hospital Cases		Deaths			Death Rate (%)		P-Value	Observed/Expected	Risk-Adjusted Rate		
									Observed	Confidence Interval	
		Observed	Expected	Standard Deviation	Observed	Expected				Observed	Low
A	7	0	1.2	0.85	0.0	17.1	0.184	0.00	0.0	0.0	20.1
B	25	0	3.5	1.69	0.0	14.0	0.019	0.00	0.0	0.0	13.7
C	69	4	8.7	2.50	5.8	12.6	0.037	0.46	6.7	0.0	14.8
D	98	11	16.5	3.43	11.2	16.8	0.068	0.67	9.7	3.8	15.6
E	420	44	66.0	7.01	10.5	15.7	0.001	0.67	9.7	6.6	12.7
F	282	35	45.6	5.74	12.4	16.2	0.037	0.77	11.1	7.5	14.7
G	116	13	14.2	3.34	11.2	12.2	0.434	0.92	13.3	6.6	19.9
H	98	17	13.6	3.21	17.3	13.9	0.182	1.25	18.1	11.4	24.8
I	29	9	5.8	2.01	31.0	20.0	0.093	1.55	22.5	12.6	32.3
County Total	1,144	133	175.1	11.37	11.6	15.3	Z-score = -3.66				

The importance of statistical variability is highlighted by the confidence intervals associated with the risk-adjusted death rates reported for each hospital. To illustrate this, Table 2 presents AMI data for nine hospitals from across the state, selected to represent a hypothetical county. The hospitals have been ordered from low to high according to their risk-adjusted death rates, using all three years of data combined. The risk-adjusted death rates range from 0% to 22.5%. The risk-adjusted death rate represents what a hospital's death rate would have been, if its patients' risk profile had been equal to the statewide average.

Hospitals A and B appear at the top of the list because they had no deaths. However, this cannot be interpreted to mean that they had the best outcomes for heart attack patients. Hospital A had only seven AMI cases, a very small number for statistical inference. The expected number of deaths at this hospital was 1.2. While the observed number of deaths was less than the expected number, this result could be due to chance alone and is not statistically significant. This is shown by the p-value of 0.184, which indicates

that with such a small number of cases, one would expect to observe zero deaths 18.4% of the time just by chance.

The absence of any deaths among the 25 patients at Hospital B is more unusual. The expected number of deaths was 3.5, and the p-value indicates that one would expect to observe zero deaths only 1.9% of the time, if there were many identical hospitals. With 402 hospitals in the state included in the heart attack analysis, chance alone would account for eight hospitals (1.9% times 402 = 7.6) having such extreme values just by chance.

In the *User's Guide*, both Hospital A and Hospital B would be labeled with a check mark in a box (☑). Neither hospital was significantly different than expected at a p-value of 0.01, but neither had any deaths.

Note that Hospital E, which ranks fifth in this county in terms of risk-adjusted rates, is the only one that would be labeled with a star (★) in the *User's Guide*, as indicated by its lower p-value of 0.001. This illustrates the importance of sample size in determining statistical significance. Hospitals with relatively few patients cannot be identified as having significantly better than expected results, even with very few (or no) deaths, because such results may be due to chance.

At the other extreme of the table are Hospitals H and I with risk-adjusted death rates of 18.1% and 22.5% respectively. The very high death rate at Hospital I was based on nine deaths among 29 patients, almost the opposite situation as Hospital B. The observed rate was more than 50% higher than the expected rate (31.0% vs. 20.0%). Even so, a result this extreme or worse is likely to occur just by chance about nine times out of a hundred, as indicated by the p-value of 0.093. Even using the standard cut-off for a p-value of 0.05 or less, this is not a statistically significant result.

Why Ranking is Inappropriate

The dangers of ranking hospitals are illustrated by the lower and upper confidence bounds around each hospital's risk-adjusted death rate. These represent the bounds within which the true risk-adjusted rate would be expected to lie, given the role of chance and the observed rate. For example, Hospital B's true risk-adjusted rate might have been as high as 13.7% despite having zero deaths. If this were the case, Hospital B would rank seventh out of the nine hospitals in this county, instead of first or second. Even if everything remained the same in terms of the quality of care, numbers of patients, and average risk among these hospitals, a change in ranking this large could be observed just due to chance variation. Likewise, Hospital I, with the highest risk-adjusted death rate, could have a rate as low as 12.6%, which would rank it seventh in this county. Potential problems in using rankings are exacerbated if one considers rankings based on the entire state. For the purposes of illustration, the nine hospitals in Table 2 were selected largely from the extremes of the death rate distribution. In fact, the vast majority of hospitals are in the middle of that distribution. For example, Hospital A is among dozens that would rank "first in the state" because it had

no deaths, yet Hospital G, which is near the middle in the overall list, might rank just as highly based on the lower confidence bound for its risk-adjusted rate. At the other extreme, the lower bound on the confidence interval for Hospital I, 12.6%, would rank it in the top quarter of hospitals in the state. In fact, because there are so many hospitals in the state and the confidence intervals are so wide, the range of possible ranks for many hospitals, due to chance alone, exceeds 100.

This example is meant to caution potential users of the data about the basic statistical issues involved in using such information. It is important to note that unusual events do happen by chance, so that a single set of results provides little information. However, if "unusual" results occur repeatedly, they may bear further investigation. Thus, hospitals with "extreme" results three years in a row are likely to have some consistent factors producing those results.

How These Data Might Be Used

It is important to recall that most statistical problems in interpreting these data arise when one focuses on death rates, because deaths are relatively unusual occurrences. Analyses of more frequent outcomes would be less susceptible to chance variation and potentially more informative.

Examine Individual Hospital

For example, one may ask whether special circumstances accounted for the very small number of AMI patients at Hospital A. With roughly one admission every other month, staff may not be ready for such emergency admissions. If Hospital A is in a very isolated area and is the only local provider, this low volume may be quite appropriate. The high expected death rates in Hospital A suggest that Hospital A's patients may be too high-risk to transfer elsewhere.

Another suggestion would be to examine hospitals with unusually low or high expected death rates. A hospital's expected death rate is a measure of the average severity-of-illness of its patients, compared with patients at other hospitals and statewide. Hospitals with low expected death rates may be referring high-risk patients from their emergency departments to other hospitals with more specialized facilities. In most areas, that would represent an appropriate referral practice. Alternatively, they may be failing to report some of their patient's risk factors. Hospitals with high expected death rates may be located near a retirement community or other high-risk population, may accept especially high-risk patients from other hospitals, or may over-report risk factors relative to other hospitals.

Examine Groups of Hospitals

One might also combine results for hospitals grouped in various ways. Grouping adds to the sample size and thus reduces the role of chance variation in explaining unusual outcomes. However, the grouping should be related to important underlying characteristics, such as the size of a hospital or its location. Hospitals also might be grouped according to health plan affiliations in a managed care environment. For readers' convenience, this volume includes a summary table for each county, which groups all of the hospitals in that county.

To illustrate grouping, consider the bottom part of Table 2, where the outcomes for all nine hospitals in a hypothetical county are aggregated.

There were a total of 133 deaths among the 1,144 patients, while 175.1 were expected given their risk factors. This results in an overall death rate of 11.6%, compared to an expected rate of 15.3%. If the number of expected deaths is five or more, one can use the following formula to determine whether there is a statistically significant difference:

$$Z = I * (ABS(NDEAD - NEXP) - 0.5) / STDDEV$$

where $I = (NDEAD - NEXP) / ABS (NDEAD - NEXP)$

where NDEAD is the number of patients who died, NEXP is the number of patients expected to die, and STDDEV is the standard deviation around the observed number of deaths for the group of interest, in this case a hypothetical county. The detailed statistical tables list this standard deviation for each model and each hospital. To calculate the standard deviation for a group of hospitals, square the standard deviation for each hospital in the group (using either Model A or Model B). Then add the resulting variances. Finally, take the square root of the sum of the variances to obtain the standard deviation of the observed number of deaths for the entire group of hospitals.

The resulting figure, or Z-score, can be converted to a probability with the assistance of standard statistical tables for the normal distribution. Roughly speaking, Z-Score values greater than 1.96 or less than -1.96 indicate that a result is statistically significant at the 0.05 level. This means these results are likely to occur by chance less than one time out of 20. The resulting Z-score for this set of nine hospitals is -3.66, with a negative value indicating that the death rate was lower than expected. Standard statistical tables for the normal distribution indicate that a Z-score of -3.66 is associated with a probability of less than 0.001. This result is likely to occur by chance less than one out of a thousand times. Thus, overall outcomes in this county were significantly better than expected, even though the hospitals in this group had worse than expected outcomes.

Data File Record Layout

There are four data files, one for each individual year 1996-1998, and one for all three years combined. The layout of each file is the same. These files are available on OSHPD's web page at www.oshpd.state.ca.us/hpp/chop.

COLUMN	COLUMN HEADING	DESCRIPTION
A	OSHPDID	Hospital's OSHPD ID Number
B	HOSPNAME	Hospital's Name

Hospital-Specific Tables and Graphs

The remainder of this volume consists of tables and graphs showing results for each individual hospital included in the study. Each hospital is on a separate page, listed in alphabetical order within counties. The first page of each county is a summary of the results from all hospitals in that county.
